6.8. The `yield` statement

```
yield_stmt ::=  yield_expression
```

The `yield` statement is only used when defining a generator function, and is only used in the body of the generator function. Using a `yield` statement in a function definition is sufficient to cause that definition to create a generator function instead of a normal function.

When a generator function is called, it returns an iterator known as a generator iterator, or more commonly, a generator. The body of the generator function is executed by calling the generator's `next()` method repeatedly until it raises an exception.

When a `yield` statement is executed, the state of the generator is frozen and the value of `expression_list` is returned to `next()`'s caller. By "frozen" we mean that all local state is retained, including the current bindings of local variables, the instruction pointer, and the internal evaluation stack: enough information is saved so that the next time `next()` is invoked, the function can proceed exactly as if the `yield` statement were just another external call.

As of Python version 2.5, the `yield` statement is now allowed in the `try` clause of a `try` ... `finally` construct. If the generator is not resumed before it is finalized (by reaching a zero reference count or by being garbage collected), the generator-iterator's `close()` method will be called, allowing any pending `finally` clauses to execute.

For full details of `yield` semantics, refer to the Yield expressions section.

Note In Python 2.2, the `yield` statement was only allowed when the `generators` feature has been enabled. This `__future__` import statement was used to enable the feature:

```
from __future__ import generators
```
